- Tetracalcium aluminoferrite (C4AF)

These compounds are finely ground to produce cement powder. Each component plays a specific role in the hydration process, influencing the setting time, strength development, and durability of the final product.

Hydration Process

The hydration of cement is a chemical reaction between the cement particles and water, leading to the formation of various hydrated compounds that give cement its strength. Key stages include:

- **Initial hydration:** Rapid reactions occur immediately upon water contact, forming surface films on cement particles.
- **Dormant period:** A period of slow hydration where the setting begins.
- **Acceleration phase:** Hydration rates increase, forming calcium silicate hydrate (C-S-H) gel and calcium hydroxide (CH), which contribute to strength.
- **Deceleration and long-term hydration:** The rate slows as available reactive phases diminish, but continued strength gain occurs over time.

Nicolas B Winter emphasizes that the microstructure formed during hydration dictates the mechanical properties and durability of cementitious materials.
