- Keyboards and mice
- Printers
- Disk drives and storage devices
- Displays and monitors
- Network interfaces
- Sensors and actuators in embedded systems

Peripherals communicate with the microprocessor to send or receive data, enabling user interaction, data storage, communication, and control functions.

Role of the Microprocessor in Data Transfer

The microprocessor acts as the brain of the system, managing data flow between itself and peripherals. It employs various techniques and control mechanisms to facilitate efficient, reliable data transfer. The choice of data transfer method impacts system performance, complexity, and cost.

Data Transfer Techniques Between Microprocessor and Peripherals

Data transfer techniques are broadly categorized based on how the microprocessor interacts with peripherals. The main techniques include Programmed I/O, Interrupt-Driven I/O, and Direct Memory Access (DMA). Each method has distinct operational characteristics suited for different applications.

1. Programmed I/O (Polling Method)

Overview:

In programmed I/O, the CPU actively manages data transfer by polling the status of the peripheral device. The processor repeatedly checks status registers to determine if the device is ready for data transfer.

Operation:

- The CPU reads a status register of the peripheral.
- If the device is ready, data is transferred.
- The process repeats until all data is transferred.

Advantages:

- Simple to implement.
- Suitable for slow peripherals with low data transfer rates.

Disadvantages:

- Inefficient, as the CPU wastes cycles polling devices even when they are not ready.
- Not suitable for high-speed peripherals.

Applications:

Primarily used in low-speed or simple devices where complexity needs to be minimized.

2. Interrupt-Driven I/O

Overview:

In interrupt-driven I/O, peripherals notify the microprocessor when they are ready to transfer data via interrupts. This method allows the CPU to perform other tasks and respond only when necessary.

Operation:

- The peripheral raises an interrupt request (IRQ).
- The microprocessor pauses current tasks and executes an Interrupt Service Routine (ISR).
- The ISR handles the data transfer.
- The CPU resumes normal operation.

Advantages:

- More efficient than programmed I/O.
- CPU is freed from continuous polling.
- Suitable for moderate to high-speed peripherals.

Disadvantages:

- Increased complexity due to interrupt handling.
- Potential for interrupt conflicts or priority issues.

Applications:

Common in systems requiring responsive devices, such as keyboards, mice, and network interfaces.

3. Direct Memory Access (DMA)

Overview:

DMA allows peripherals to transfer data directly to or from memory without involving the CPU for each byte or word transferred. A dedicated DMA controller manages the data transfer.

Operation:

- The CPU initializes the DMA controller with transfer parameters.
- The DMA controller manages data transfer independently.
- Once transfer completes, the DMA controller signals the CPU via an interrupt.

Advantages:

- High efficiency and minimal CPU involvement.
- Ideal for large data transfers like disk I/O or audio/video streaming.

Disadvantages:
